

Chapter 11

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

Signpost to Chapter 11

There are theory, practice, and history, in any science. This chapter sums up KEWT data-sets empirically from the viewpoint of economic stages and growth. The economic stages, however, are transparent historically and philosophically. Since Smith Adam (1776), almost two centuries and a half have passed. Except for the last half century, scholars and economists had studied and solved economic growth problems, without national accounts calculation system. Economic theories, nevertheless, had progress strongly step by step, like weeds, without fertilizer or tests for theories. In the meantime, leaders and people had experienced the Industrial Revolution for the first time in human history. It is surprising for scholars to create economic theories decade after decade, even in the times of no statistical-data.

Kuznets, S. (1941, 1952, 1966, 1971) had continuously researched economic stage and growth by country. In the 1960s, the data-sets were rough compared with the latest data after the 2000s. Scholars and economists even today consent that Schumpeter, J. A. (1912, 1938, 1954) is the Father of modern economics for technological progress. Economic theories including Schumpeter's, however, are all demand and supply price-oriented even up to date. The author here loudly indicates that this price-oriented stream had brought about wars after wars. What is its foundation? In earlier days of Smith and Ricardo, it was thought that an economy or nation converged to the steady state and finally creased growth. To avoid no growth, an open economy was needed and divided into two: security first and free trade first. To maintain growth and drive the steady state away, technological progress is a universal means. Nevertheless, human behavior wants more money endlessly and is inclined to control other countries with power, under a big wave for colonialism, and repeats wars to solve problems, within and out of nations.

The author pays attention to heterogeneous culture and history by area, as well recognized by Kuznets. This philosophy needs two paradigm rotations of theories and methodologies. Needless to say, the first rotates from the price-equilibrium to the endogenous-equilibrium; the second rotates from homogeneous to heterogeneous. All problems are solves endogenously cooperatively and peacefully. Historical review and revisit of the literature clearly prove these rotations are true, without unemployment and

Chapter 11

with a low inflation. And, these rotations co-exist with the current modern economics. Now, macroeconomics¹ independently is Mother as Chapter 1 clarified the base.

This chapter does not step into the above history. Instead, in conclusion at the end, the author refers to several articles related to technological progress policy in Singapore, China, and Mexico, after briefly reviewing ‘competitiveness report.’

11.1 Introduction

The current stream in developing countries quantitatively makes them hurry up in order not to be behind other countries. The author feels this atmosphere at G7, G20, and other conferences, 2012. It is of course natural that we need growth for full-employment even under tight budgetary control. The author, however, proves that for this reason each country must choose the best second path that guarantees sustainable growth as a short cut and in reality. This chapter takes advantage of six organic aspects and empirically clarifies facts and methods to the correct path policy-makers all look for with feverish eyes, as we run after Blue Birds.

This chapter examines and summarizes different transition processes from young-developing to robust-developing and, further to developed stages, by country. African countries are not included in this chapter because KEWT series have not enough data-sets by country for African area, in particular, deficit by year and over years. This chapter also does not concretely step into developed stage countries. The developed stage is separately discussed in other chapters as recognizably by those titles of fiscal policy or fiscal multiplier and the size of government. This chapter, finally in Conclusion, refers to the current variety of articles, compares, and comments each methodology. What elements guarantee stable growth by country? This is the purpose of this chapter.

There are two problems for the characteristics of the economic stages: 1) the characteristic *common* to a country at an economic stage and 2) the characteristic *peculiar* to each stage. The common characteristic is the endogenous structure of the balance of payments and deficit. Firstly, the endogenous structure of the balance of payments differs from the structure of the balance of payments in the literature since the literature treats it from the viewpoint of the financial assets-side while the author’s from the real-assets side. Conclusively, if the endogenous structure overruns a moderate range of the

¹ Macroeconomics is most fitted for pursuing true results as a unit of causes and effects since Smith (1776). The private sector is most fitted for pursuing business cycle since Schumpeter (1928). Jorgenson, D. W., and Griliches, Z. (1967) rotates one paradigm from stock to flow as capital investment for technological progress (for simultaneous measure of flow and stock of capital, see Chapter 6). This rotation needs one more rotation of the consistency between flow and stock (see, Chapter 16). Macroeconomics endlessly continue to grow, generation after generation in the endogenous system. Right now, leaders and policy-makers are able to focus on green/eco economics. Green/eco buries holes to fall into, since world resources are limited and we endogenously attain maximum returns under minimum net investment, as shown by hyperbola and its graph (see, Chapters 7 and 15).

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

endogenous-equilibrium or becomes extremely unbalanced, any country cannot maintain a sustainable rate of technological progress. Secondly, the peculiar characteristic varies by economic stage. This chapter treats sixteen cases of the transition processes at the young-developing stage beginning in 1990. Some countries grew steadily and got into the next stage while others moved back and forth for the last twenty years. There may be peculiar reasons, partly due to strong personality of national taste/preferences, culture, and history by country.

My questions are: Why do some young-developing countries conquer their difficulties and get into the next stage while others stay at the same stage up and down for many years? Do young-developing countries have their own peculiar difficulties at each economic stage, compared with developed countries? Behind these questions, there exists human philosophy. The higher the wave rays the more calm an economy is. The earth is the place where we human and people live together peacefully with other living animals and vegetation. Strong personality by country may or may not fight against high wave rays of human itself.

The original actual statistics data are obtained from *International Financial Statistics Yearbook*, IMF. The author selects sixteen young-developing countries in Asia, Latin America, and Near East; Turkey, Ukraine, Kazakhstan, Pakistan, Bangladesh, Indonesia, Philippines, Sri Lanka, Vietnam, Mexico, Argentina, Bolivia, Chile, Columbia, Paraguay, and Peru.

Before starting, the author wholly sketches the endogenous model and system in this section. This sketch is also necessary for setting up two methods to observe and examine the above different characteristics. Two methods are *six* organic aspects and *five* pattern-settings. The background of the two methods will be gradually clarified by sketching the endogenous model and system.

The endogenous system connects theory with its practice and integrates into a system as one simultaneous unity. The endogenous model starts with Solow's (1956) model but, definitely replaces exogenous by endogenous and endogenously measures the rate of technological progress. The endogenous model always holds in the endogenous-equilibrium. The rate of technological progress and all others are each expressed by two ways: (1) at convergence in the transitional path and (2) at the data-sets by year as the unity of theory and practice, where (1) and (2) are consistent by year and over years. The rate of technological progress, the growth rates of capital, the rate of return endogenously, and other parameters and variables are all simultaneously measured using a 'discrete' Cobb-Douglas production function that involves *seven* endogenous parameters.

The literature, without exception, distinguishes a model with its actual data used for the model: 'Estimated parameter' is distinguished with 'calculated variable,' under the use of actual 'panel' data. 'Forecasting' shows a result of variables after independent

Chapter 11

variables were inserted into the model. ‘Ad hoc’ is never general and means ‘once for all’ or ‘for specific purpose or situation at hand.’ Independent variables constitute causes and dependent variables constitute results under various functions. Each model is separated so that an integration of all possible models is impossible, in particular when optional actual data are used independently of the model.

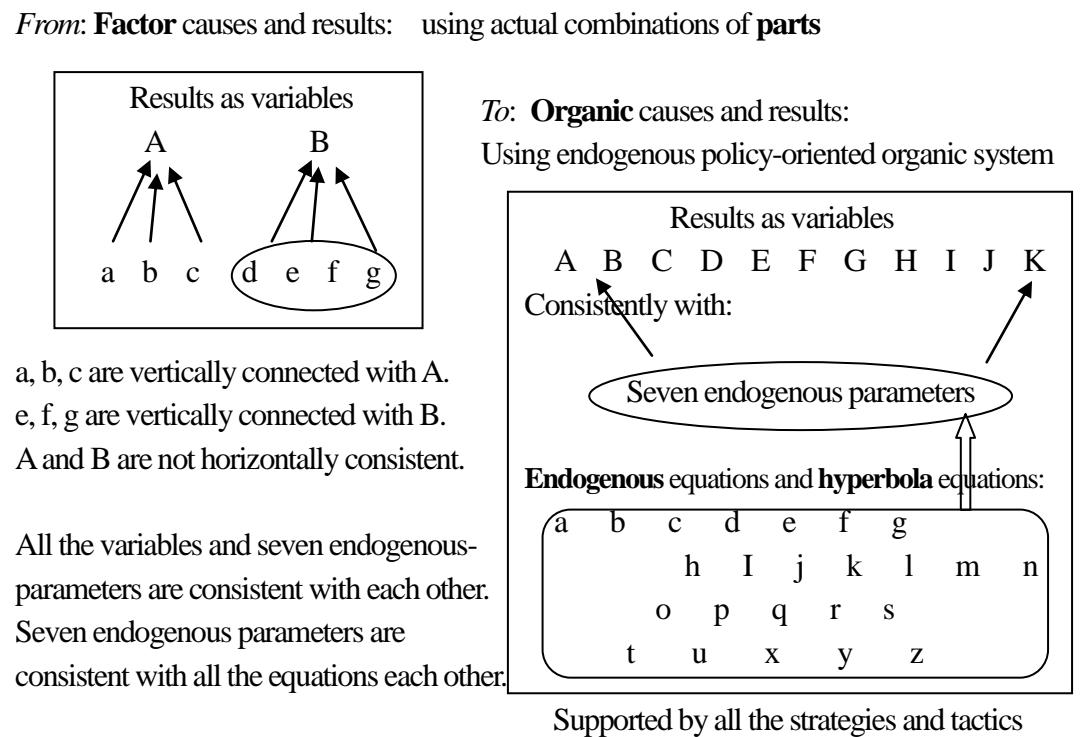

The endogenous system, contrarily, reverses the above concepts and definitions completely. This system does not distinguish estimate with measure since the system measures all the data after converting actual data to endogenous data. Measurement is most strict to the extreme and, differs from the concepts of estimate, calculate, and forecast. Endogenous data change, by item, year, country, and sector; never repeating again over years, just like ad hoc. Endogenous data, nevertheless, always consistently with each other, just like or similarly to the cases of actual data in this world. Forecast may be expressed as a case when actual data are replaced by forecasted data. Due to one theory and practice unity, causes and results at endogenous data simultaneously occur by year. Policy-oriented causes are only expressed by seven endogenous parameters and accordingly eight policy determinants by year. Results are all endogenously expressed by parameters and variables by year. Strategies and tactics are all absorbed into seven endogenous policy-oriented parameters.

Let the author now connect the endogenous model and system with six organic aspects and five pattern-settings: The endogenous policy-oriented organic system (hereafter, the endogenous system) is based on the ‘discrete’ Cobb-Douglas production function in the endogenous-equilibrium, where seven endogenous parameters are first measured using endogenous equations and corresponding hyperbolic equations. The endogenous-equilibrium is measured by endogenous speed years by country and sector. The financial and market assets are supplemental and indirectly involved in the real assets of the endogenous system, due to the neutrality of the financial and market assets to the real endogenous assets by year. The endogenous system is wholly and broadly examined by six organic aspects by country. If the levels of six organic aspects are all well balanced, a country as an economic organ maintains robust sustainable equilibrium. Six organic aspects, however, are difficult to take out one by one.

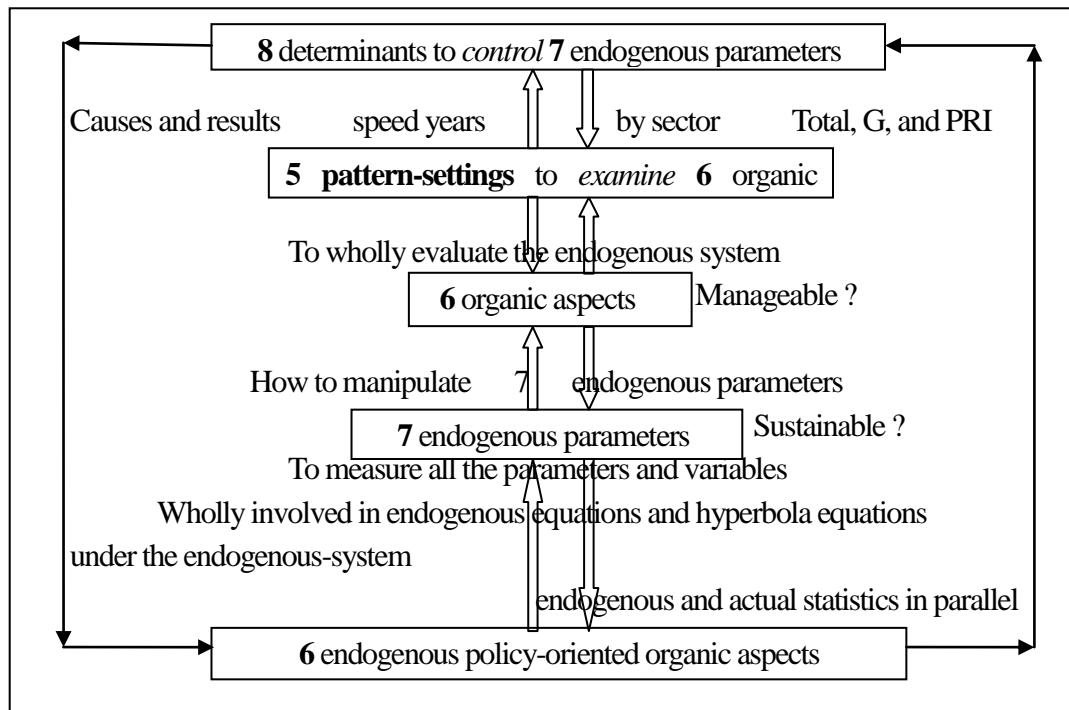

In order to solve this problem in six organic aspects, the author introduces two new devices; (1) ‘eight policy determinants’ to *control* seven endogenous parameters and (2) ‘five pattern-settings’ to *examine* six organic aspects. A series of BOXES are shown. Eight policy determinants are overlapped with seven endogenous parameters and six organic aspects and, most fitted for five pattern-settings, free from sticky explanations of endogenous and hyperbolic equations, as shown in **BOX 11-1**.

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

BOX 11-1 A shift of paradigm of causes and results: vertical versus wholly

BOX 11-2 Endogenous parameters, organic aspects, and pattern-settings in the endogenous system

Chapter 11

BOX 11-1 shows the background of the endogenous-system from the viewpoint of causes and results and clarifying the differences between vertical and whole. Data use statistics but no external. Data are all converted to endogenous as a whole system, starting with simultaneous measurements of capital and the rate of return.

BOX 11-2 is designed for evaluating stage processes by country and shows up *five* pattern-settings that take advantage of basic endogenous ratios.² Pattern-settings are mostly based on *six* organic aspects (for *six* organic aspects in detail, see Notations at the beginning of Monograph). Background of *five* pattern-settings is endogenously related to all of i) seven endogenous parameters, ii) eight policy determinants, and iii) six organic aspects.

The items related to *five* pattern-settings are the following.

- i) *Seven* endogenous parameters are: the relative share of capital α ; the growth rate of population n ; the ratio of net investment to output $i = I/Y$; the qualitative net investment coefficient β^* ; the diminishing returns to capital (DRC) coefficient δ_0 ; the capital-output ratio Ω ; and, the ratio of government net investment to government output $i_G = I_G/Y_G$.
- ii) *Eight* policy determinants: (1) the balance of payments and debt, (2) endogenous taxes, (3) marginal rate of substitution, (4) marginal productivities of labor and capital, (5) the elasticity of substitution, (6) the relative share of capital, (7) the speed years for convergence, and (8) the capital-output ratio.
- iii) *Six* organic aspects: for simplicity, *eight* policy determinants are used as a surrogate.

The items *five* pattern-settings directly treat are: (1) the balance of payments and deficit, (2) the relative share of capital, (3) possibility of full-employment, (4) the real cost of capital, and (5) the endogenous valuation ratio.

Sixteen countries have each its own policies and policy-changes by year. The results

² Basic endogenous equations in the endogenous model/system:

1. The capital-output ratio, $\Omega = K/Y$: $\Omega^* = \frac{\beta^* \cdot i(1-\alpha)}{i(1-\beta^*)(1+n)+n(1-\alpha)}$.
2. The qualitative coefficients, $beta^*$: $\beta^* = \frac{\Omega^*(n(1-\alpha)+i(1+n))}{i(1-\alpha)+\Omega^* \cdot i(1+n)}$.
3. The coefficient of diminishing returns, $delta_0$: $\delta_0 = 1 + \frac{LN(\Omega^*)}{LN(B^*)}$ and $B^* = (1 - \beta^*)/\beta^*$.
4. The level of technology (as stock): $A = TFP = k^{1-\alpha}/\Omega$.
5. The relative price level, p : $p=1$ always holds using $p \cdot Y = w \cdot L + r \cdot K$ in the transitional path and the data-sets.
6. The relative share of capital, $\alpha = \Pi/Y$: $(1 - \alpha) = \frac{c}{(rho/r)}$, $\frac{K}{L} = \frac{(\alpha/(1-\alpha))}{(r/w)}$, and $k = \frac{w \cdot \Omega}{1 - r \cdot \Omega}$.
7. $\sigma = 1.0 = \frac{\Delta k/k}{\left(\Delta \left(\frac{r}{w}\right)\right)/\frac{r}{w}}$ holds in the transitional path.

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

examined by *five* pattern-settings considerably differ by country. Each country maintains endogenous equilibrium by reducing inevitable unbalances between seven endogenous parameters. Seven endogenous parameters measures the level of endogenous equilibrium but, differently. This is because each country has its own national taste/preferences, culture, and technology, even in the global economies. Diversification and Globalization do not endogenously contradict and cooperate with each other. Some countries still cannot get rid of difficulties; such as Pakistan, staying at the same economic stage. A country cannot always grow fast and needs its own vision far ahead, partly due to the possibility of excessive unbalances in seven endogenous parameters. Extreme unbalances of the total economy are further aggravated by the unbalances between the government and private sectors. Unbalanced relationships between the government and private sectors are a key for conquering and controlling difficulties at any economic stage.

11.2 How to Classify Six Organic Aspects to Conquer Difficulties at an Economic Stage

There are six organic aspects for any country to conquer difficulties by economic stage (poor, young-developing, developing, and developed). A young-developing country cannot easily get into a stable developing stage. Why does this occur? It implies that six organic aspects are too burden at young-developing stages. The characteristics at the beginning are low *GDP* per capita, low education, and considerably less jobs, with insufficient infrastructures.

In the endogenous system by country, the policies and policy-changes are all absorbed into seven endogenous parameters that digest rival factors, labor and capital. Strategies and tactics all absorb non-rival factors such as education, R & D, and learning by doing and are wholly filtered into policies and policy-changes measured by seven endogenous parameters. Then, how to control endogenous parameters? Seven endogenous parameters (results) are controlled by changing eight policy determinants (causes). Endogenous ‘causes and results’ circulate at the real assets and, the cause-determinants are eight policy determinants. For example, the rate of unemployment and some level of inflation are results of the real assets in equilibrium. Infrastructures are expressed by seven endogenous parameters using flow and stock of capital in equilibrium by sector (the total economy, and the government and private sectors).

Endogenous equilibrium is a surrogate of the price-equilibrium that balances macro demand and supply and, measured by the speed years for convergence in the transitional path by country and year. The price-equilibrium has fostered the literature for the last three Centuries. Nevertheless, it has two critical defects: (1) it is not always measured consistently within a whole system of an economy and (2) it cannot consistently measure cases of disequilibrium. In other words, the price-equilibrium is measured only after

Chapter 11

settling disequilibrium, where disequilibrium recovers simultaneously (with government cash flow-out by deficit). Disequilibrium does not actually. Even national bankruptcy holds at a close-to-disequilibrium and, before hitting actual disequilibrium. For example, countries had fallen into bankruptcies, as IMF tried to help recovering Argentina, Malaysia, and Korea.

Eight policy determinants are explained using equations step by step as follows: (1) The balance of payments and deficit each to endogenous income Y , $bop = BOP/Y$ and $\Delta d = \Delta D/Y$; (2) endogenous taxes that determine the size of government, $tax = Y_G/Y = T_{AX}/Y$; (3) the marginal rate of substitution, $MRS=r/w$, where ‘ r ’ is the rate of return and ‘ w ’ is the wage rate each in equilibrium; (4) the marginal productivity of labor, $MPL=w$, and the marginal productivity of capital, $MPK=r$, under the relative price level $p=1.0$; (5) so called *sigma*³ as an endogenous surrogate for the wage index in statistics; (6) the (endogenous) relative share of capital $\alpha = \Pi/Y$, where Π is endogenous returns.

Then, (7) the speed years for convergence, $1/\lambda^*$, $\lambda^* = (1 - \alpha)n + (1 - \delta_0)g_A^*$, where $n = n_E$ is the rate of change in population in equilibrium; δ_0 ⁴ is the diminishing returns to capital (DRC) coefficient; $g_A^* = i(1 - \beta^*)$ is the rate of technological progress; $i = I/Y$ is the ratio of net investment to output/income; and $1 - \beta^*$ is the qualitative net investment coefficient. All of these are not assumed but measured in equilibrium consistently over years in the endogenous system; and finally (8) the capital-output ratio, $\Omega = \Omega_0 = \Omega^*$, where the above δ_0 and β^* are involved. As a result, seven endogenous parameters are measured and controlled in equilibrium.

At the above (8), the literature does not use the capital-output ratio, $\Omega = K/Y$, but the capital-labor ratio, $k = K/L$. The author here stresses two fundamental reasons why the literature does not use the capital-output ratio in the Cobb-Douglas production function. Two fundamental reasons: (1) Capital and the rate of return must be measured, at the same time as Robinson, Joan (1959) claimed, and by sector and, (2) returns by sector are difficult to measure in the case of a system of national accounts (SNA). Statistics today, including IMF, OECD, and Penn World Table (PWT 6.2), do not measure and publish neither capital stock nor the capital-labor ratio. Japan Government Office, the Bureau of Economic Analysis of Dept. of Commerce, the US, and several other countries publish capital at national accounts statistics. However, capital is estimated externally either using the perpetual inventory method at the total economy or the cost of capital market data at the corporate sector.

³ The *sigma* is similar to the literature and defined as $\sigma = \frac{-\Delta k/k}{\Delta(r/w)/(r/w)}$. In the author's discrete Cobb-Douglas production function, it is calculated as $\sigma = \frac{-\Delta k/(k_0+k_1)}{\Delta(r/w)/(\frac{r_0+r_1}{2}/\frac{w_0+w_1}{2})}$. The *sigma* fluctuates at the data-sets by sector and by year and shows that the flexibility is guaranteed. In the corresponding recursive programming, *sigma*=1.00 is proved by year at the transitional path.

⁴ $\delta_0 = 1 + LN(\Omega^*)/LN((1 - \beta^*)/\beta^*)$, where $\Omega_0 = \Omega^*$ is the capital-output ratio. The speed years terminates at convergence in the transitional path.

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

Capital and the rate of return are only measured with all the other parameters and variables at the same time. The processes to measure parameters and variables endogenously are involved in eight policy determinants. Endogenously, capital K is measured by flow and stock relationship of net investment after reducing capital consumption. The rate of return r is measured, starting with actual GDP and national disposable income (NDI) and using $tax = Y_G/Y = T_{AX}/Y$ and $i_G = I_G/Y_G$ stated above; with $MRS=r/w$,⁵ Ω , $r = \alpha/\Omega$, and $w = r/(r/w)$.

A country at any economic stage requires fulfilling six organic aspects. Causes and results do not hold independently each by each but, wholly and simultaneously at six organic aspects. As a result, any country enjoys maintaining endogenous equilibrium sustainably over years. A defect of six organic aspects exists not theoretically but by empirically. Six organic aspects should not uniformly classify young-developing countries and satisfy with arranging alphabetically these countries. These arrangements are a starting point and require whole implications through six organic aspects, with eight policy determinants.

11.3 Secret of Success to Solve Problems at Young-developing Countries

This section, for simplicity, uses eight policy determinants possibly as a surrogate for the classifications of countries based on six organic aspects. How can a young-developing country successfully enter into a robust developing stage without staying back and forth at the young-developing stage? Policy-makers' patient struggling at the young-developing stage may be similar to that at the developed stage. First of all, the balance of payments BOP and deficit ΔD stir up the situation. Policy-makers' aim is to maintain moderate endogenous equilibrium but, a moderate balance of payments and a deficit may be a prerequisite to some extent. Under equilibrium, there is no difference lying between the price-equilibrium and endogenous equilibrium. The author stresses that a moderate level of the balance of payments and deficit is a result at an endogenous equilibrium. Policy-makers' philosophy and perception of national taste and technology finally influence the level of bop and Δd . If philosophy and perception by country are widened to the earth preservation in the long run, the corresponding organic aspects may be robust and conquer various difficulties by strong leadership. Young-developing stage countries must quickly prepare for sudden risks ahead, with much room for balanced organic aspects.

⁵ The marginal rate of substitution $MRS=r/w$ is obtained by using (1) national taste, $\frac{rho}{r} = 13.301c^2 - 22.608c + 10.566$, where the propensity to consume $c = C/Y$, (2) $\alpha = 1 - \frac{c}{rho/r}$, and (3) $(r/w) = \frac{\alpha/(1-\alpha)}{K/L}$.

Chapter 11

What policy determinant is most sensitive to endogenous equilibrium at young-developing stage? This is the ratio of net investment to output/income. First, if a young-developing country could stably get net investment for many years, the country is able to proceed to the next stage. Nevertheless, the actual world differs. A reason is that a high level of net investments over years causes an unbalanced net investment between the government (G) private (PRI) sectors. What causes net investment unbalanced between government and private? Government investment may be actually processed at the PRI sector yet, pros group-oriented opinion becomes much stronger than cons, often apart from right judgments and sacrificing the PRI sector.

The author advocates here that if policy-makers knew the size of government endogenously, the results differ and, the country makes the most of resources and taste/preferences with the corresponding technology. An economy grows gradually just like a baby as an organ with its reserve power. Sustainable economy needs to be balanced by year. Many countries today, after 1997-98 financial crises, have tried to guard against outside short money, with increased savings. This is learning by doing, though against free mobility of capital as a stream.

What result must policy-makers accept when the size of government is beyond its limit? The country must lose its reserve power and the speed years will be unstably longer. A typical case is Japan's speed years, 2007 and 2009 under increasing deficits: The speed years were 313.12 at the total economy, 68.09 at the G sector, and -17.07 at the PRI sector in 2007 while 495.24, 5.04, and -101.19 in 2009 respectively. The total economy still maintains equilibrium in 2009 but, the G and PRI sectors are already out of equilibrium. Huge deficit by year is one of results. It implies that Japan lost its reserve power due to the increase in deficits and debts over years. A young-developing country cannot raise actual taxes so that the difference between actual and endogenous taxes must be smaller than that of developing and developed countries. The young-developing country cannot eat too much.

Under these circumstances, young-developing countries have often suffered from high inflation. The rate of inflation is usually watched by Consumers Price Index (*CPI*). The literature assumes that the rate of inflation is externally given. Six organic aspects, differently from a common sense, have the rate of inflation endogenously measured. This clarifies that higher inflation is inevitable when an economy grows at a higher rate. If a young-developing country suffers from high inflation under a low growth, it means that policy-makers cannot find a sustainable combination of policies and endogenous parameters or that the corresponding six organic aspects become more wholly unbalanced. This is true even if deficit is not a burden so much. Policy-makers look for real-assets causes and pursue balanced aspects by year, improving a combination of seven endogenous parameters. Principal causes are traced back to the abnormal values of DRC coefficient $\delta_0(\Omega, \beta^*)$ and the current capital-output ratio Ω_0 .

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

The capital-output ratio spreads itself into six organic aspects along with the transition of the economic stage. At a young-developing stage country, the capital-output ratio is considerably low; e.g., less than 0.5 and/or less than 1.0. If δ_0 and β^* are unbalanced with such low levels of the capital-output ratio, the combination of seven endogenous parameters are unbalanced. To improve seven endogenous parameters, policy-makers need to control eight policy determinants and widely execute fulfilling strategies and tactics by year. Along with the improvement in seven endogenous parameters, the speed years will enter a moderate range of equilibrium.

For strategies, a young-developing country consecutively executes higher education in the long run and increase employment. As a result of higher education with think of others, the quality of jobs will be higher gradually by year. Earlier economists such as Adam Smith started with full employment and today, the rate of unemployment is inevitable in the literature, as shown by huge researches related the non-accelerating-inflation rate of unemployment (NAIRU). The author stresses that the ‘endogenous’ NAIRU is involved in six organic aspects, where a low unemployment with a low inflation is within hands. It is true that when seven endogenous parameters are well controlled using policy determinants, full employment and low inflation are attained, as shown empirically using the data-sets of 65 countries at KEWT 5.11 by sector.

The relationship between the rate of return and the rate of u-, full-, and over-employment is theoretically proved by using the rate of return hyperbola equation, $r(n, \alpha, i, \beta^*)$. The upper limit of endogenous inflation is shown by its horizontal asymptote (HA) and full employment is shown as a case that the actual growth rate of population equals the endogenous rate of change in population in equilibrium, $n = n_E$. The upper limit of the capital-output ratio distresses developed countries and is shown by the horizontal asymptote (HA) of $\Omega(n, \alpha, i, \beta^*)$.

Finally, the author summarizes this section by stressing the use of an equation of $\alpha = \Omega \cdot r$. This is a core of seven endogenous equations and respective hyperbola equations. This equation influences commonly to all of economic stages and most severely to the young-developing stage. Young-developing stage countries each have a low relative share of capital α , which demands a soft balance between the capital-output ratio Ω and the rate of return r . Some developing countries show a high level of α , but Ω and r are not backed to steadily guard the low α . For a balanced maintenance of $\alpha = \Omega \cdot r$, $\Omega(n, \alpha, i, \beta^*)$ need to cooperate with $r(n, \alpha, i, \beta^*)$ (for each equation, see Appendix). A bad interruption is bubbles of flow (uncontrollable inflation) or stock (irresponsible asset bubble). Six organic aspects fuse eight policy determinants, the upper limit of inflation, and the endogenous valuation ratio, $v^* = V^*/K$. Seven endogenous parameters must have a room for reserve power to control each other: not to grow too high but to be balanced.

Chapter 11

11.4 Five Pattern-settings to Examine Balanced Levels by Country

This section is a highlight of this chapter. The author selects sixteen countries: Turkey, Ukraine, Kazakhstan, Pakistan, Bangladesh, Indonesia, Philippines, Sri Lanka, Vietnam, Mexico, Argentina, Bolivia, Chile, Columbia, Paraguay, and Peru. The author does not include African and Near East countries, partly due to widely-ranged qualitative differences of data disclosed at *International Financial Statistics Yearbook*, IMF. It is true that peaceful world economies are guaranteed by stop-inequality. Stop-inequality has two aspects: macro and micro, where endogenous policies absorb all the strategies and tactics, through seven endogenous parameters. If seven endogenous parameters are controllable, stop-inequality spreads over causes and results. Six organic aspects are endowed with stop-inequality. The speed years are endowed with endogenous equilibrium. In the long run, there is no contradiction between the speed years and stop-inequality yet, in the short run there is some contradiction. This is because excessive policy to stop-inequality decreases steady growth for the future. This kind of contradiction is also adapted to a case of excessive deficit. Contradiction is mitigated by balanced pattern-settings.

Data source: KEWT 5.11-5 by sector, 1990-2009, whose original data are from *International Financial Statistics Yearbook*, IMF. KEWT 5.11-5 Data-source of Tables A2-3 and A3-3 is each the same.

This section examines and evaluates results of each country by using five pattern-settings. Five pattern-settings are: (1) The balance of payments and deficit; (2) The relative share of capital; (3) The relationship between the growth rate of population

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

and the rate of change in population in equilibrium; (4) The real cost of capital; and (5) The valuation ratio as a whole evaluator of seven endogenous parameters and eight policy determinants. Each country has conquered its own unbalanced situations by year. Therefore, each of five pattern-settings differently reveals unbalanced determinants. Five pattern-settings are conclusively shown by using BOX 11-3, 11-4, and 11-5. The author explains each of a series of BOXES step by step after **BOX 11-3**.

The author examine sixteen countries, using the 1st pattern-setting to $bop = \Delta d + (S_{PRI} - I_{PRI})$, where $bop = BOP/Y$ is the balance of payments to output/income Y , $\Delta d = \Delta D/Y$ is deficit to Y , and $(S_{PRI} - I_{PRI})$ is the difference between saving and net investment at the private (PRI) sector. The data-sets of KEWT 5.11, 1990-2009 by sector is used for this pattern-setting. The above pattern-setting examines twenty year tendency of bop , Δd , and $(S_{PRI} - I_{PRI})$, by giving ‘plus and minus signs’ to three of bop , Δd , and $(S_{PRI} - I_{PRI})$, just like +, +, + or +, -, +. For this pattern-setting, the author simultaneously takes into consideration the smoothness of the speed years. Note that Pattern, +, +, +, is not always sustainable, partly due to the decrease in domestic net investment. There are *four* patterns and each corresponding countries are as follows:

- 1. Pattern Balanced: +, -, +, or -, +, + balanced and robust.
- 2. Pattern Temporal: +, +, +, or, +, +, -, or -, -, +, with strong individuality.
- 3. Pattern Difficult: +, -, -, or -, -, -, sometimes close-to-disequilibrium.
- 4. Pattern the Lowermost: -, -, -, often falling into disequilibrium.

Pattern Balanced: Argentina, Colombia, Paraguay, and Peru.

Pattern Temporal: Bangladesh, Indonesia, Philippines, Sri Lanka, Vietnam, Bolivia, and Chile.

Pattern Difficult: Turkey, Ukraine, Kazakhstan, and Mexico.

Pattern the Lowermost: Pakistan.

Let the author similarly examine sixteen countries, using the 2nd pattern-setting to different levels of the relative share of capital at $\alpha = \Omega \cdot r$, and following the data-sets of KEWT 5.11, 1990-2009 by sector. Each of sixteen countries has its own characteristics in six organic aspects. The above pattern-setting examines sixteen countries by twenty year transition of unbalanced growth and stop-inequality. For this pattern-setting, the author simultaneously takes into consideration the sign of DRC coefficient, δ_0 , for the last ten years. There are *four* patterns originally defined and corresponding countries are as follows:

- 1. Pattern Smooth: $0.15 < \alpha < 0.25$, balanced and smooth.
- 2. Pattern Irregular: $0.05 < \alpha < 0.125$ or $0.30 < \alpha < 0.50$, with strong individuality.
- 3. Pattern Difficult: α unstable and fluctuating, sometimes close-to-disequilibrium.
- 4. Pattern the Lowermost: α most unbalanced, often falling into disequilibrium.

Chapter 11

Pattern Smooth: Bangladesh, Indonesia, Philippines, Sri Lanka, Vietnam, Chile, Colombia, Paraguay, and Peru.

Pattern Irregular: Ukraine, Mexico, and Argentina.

Pattern Difficult: Turkey, Kazakhstan, and Bolivia.

Pattern the Lowermost: Pakistan.

The above results are interpreted wholly: Young-developing stage countries have each national taste/preferences even in the global economies in the world today. Each country has different policies for the last twenty years yet, for the last ten years, many countries have adjusted their policies much more than expected, particularly at Asian and Latin American countries. Most countries show minus balance of payments yet, this minus is within a range and contributes to each country's growth in the long run. Each country has its own strategy for coping with a minus balance of payments and also a minus deficit within some ranges. What does urge each country to have its own policy? This is endogenous equilibrium. Each country does not actually measure endogenous equilibrium but, each country manipulates policies towards equilibrium. As a result, a moderate range of endogenous equilibrium is maintained but, its approach differs by country. No country takes same policies or strategies. This fact is proved by confirming various variables and endogenous parameters—not only through the review of seven endogenous parameters but also through hundred related parameters. A certain level of growth is not obtained by the guidelines in the textbooks. This is an implication of the above two pattern classifications.

In general, most countries are divided into two patterns; low versus high relative share of capital. Then, does a country with a low relative share of capital sacrifice stop-inequality? Or, does a country with a high relative share of capital a country sacrifice stop-inequality? The author denies both. Each country executes each preferable policy or has to do so under people's votes and elections. Then, why must a country take a policy of high relative share of capital despite a fact that the higher the relative share of capital the more distribution to capital is anticipated? The interpretation is: a young organic economy must be balanced as much as possible but, factors and resources have more restrictions so that unbalanced conditions result in a high relative share of capital. Each country's people historically know the responsibility for each own rights and duties, after long failures and experiences. When each country survives with less help from others, the world economies become more stable and peaceful. Each country becomes 'think of others' and cooperates with each other. This is a good point of globalization. Globalization cooperates with national taste/preferences and culture. In fact, each country never have has the same pattern. It is difficult for policy-makers to examine and confine each country into a certain pattern.

Let the author examine sixteen countries, using the 3rd pattern-setting to different levels of the unemployment at the total economy by $n_E - n$, similarly to the above two

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

pattern-settings. Theoretically, there is no unemployment in equilibrium at any economic stage. And this fact encourages policy-makers to approach full-employment. There are *three* patterns defined, by year during 1990-2009, and each corresponding countries are as follows:

1. Pattern Robust: $n_E - n = 0$ by year, balanced and smooth.
2. Pattern Usual: $n_E - n \neq 0$, a few times in earlier 1990s and 2009, sometimes close-to-disequilibrium.
3. Pattern Difficult: $n_E - n \neq 0$, repeatedly, often falling into disequilibrium.

Pattern Robust: None.

Pattern Difficult: Turkey, Ukraine, Bangladesh, Indonesia, Sri Lanka, Vietnam, Mexico, Argentina, Chile, Colombia, Paraguay, and Peru.

Pattern Difficult: Kazakhstan, Pakistan, Philippines, and Bolivia.

All the countries enjoy full-employment in equilibrium, except for the above four countries. Unemployment occurs only in 2009 and/or one or two times during the 1990-93. Even the above four countries enjoy full-employment except for Pakistan. Pakistan must find balanced six organic aspects so that national taste and culture could accept without resistance, with steady education and FDI.

Let the author examine sixteen countries, using the 4th pattern-setting to plus/minus different levels of the real cost of capital (=the rate of return less the growth rate) by sector using $CC_{REAL(G)}^*$ and $CC_{REAL(PRI)}^*$. For this pattern-setting, the author takes ‘a plus real cost of capital at the total economy.’ The author does not deny the market rate in the long-term and proves that ten year debt yield at the market is equal to the rate of return in equilibrium by country. Plus signed high cost of capital is preferable to minus signed one. Because: (1) If the rate of return is higher than the growth rate of output, net investment is encouraged. (2) If deficit rise up beyond a certain range the cost of capital turns to minus first at the G sector. The *four* Patterns are as follows:

1. Pattern Smooth: plus $CC_{REAL(G)}^*$ and $CC_{REAL(PRI)}^*$, balanced and smooth.
2. Pattern Private-oriented: minus $CC_{REAL(G)}^*$ but plus $CC_{REAL(PRI)}^*$, with strong individuality.
3. Pattern Government-oriented: minus $CC_{REAL(G)}^*$ and $CC_{REAL(PRI)}^*$, sometimes close-to-disequilibrium.
4. Pattern the Lowermost: negatively fluctuating $CC_{REAL(G)}^*$ and $CC_{REAL(PRI)}^*$, often falling into disequilibrium.

Chapter 11

Pattern Smooth: Bolivia, Chile, Colombia, Paraguay, and Peru (though each, after 2000).

Pattern Private-oriented: Turkey, Pakistan, Bangladesh, Indonesia, Philippines, Mexico, and Argentina,

Pattern Government-oriented: Ukraine, Kazakhstan, Sri Lanka, and Vietnam.

Pattern the Lowermost: None.

Pattern Smooth is occupied by Latin American countries.

Pattern Private-oriented is occupied by Asian countries. Each case has its own series of histories and experiments in the past. Private-oriented implies that government helps develop the private sector and it has its identity. Government-oriented implies that government must lead an economy when it is young. This is justified by the fact that without leading infrastructure the economy cannot grow under the world competitions. Government-oriented, however, often falls into a minus cost of capital due to minus government rate of return, with less technology-oriented compared with private-oriented. This direction is allowed when domestic saving is high as shown in most Asian countries after 1997-98 crises. Note that the private sector actually runs even under government-orientation. Government-oriented is endogenously related to the size of government. Therefore, government-oriented never lasts as a sustainable policy. Both private-and government-oriented must be flexible so as to shift to private-oriented when an economy gets into a developed stage. The author raises a serious fact in this respect: group-oriented political powers would not accept this right timely shift at the transit of economic stages, as democratic Japan has experienced for the last twenty years.

Let the author finally examine sixteen countries, using the 5th pattern-setting to the valuation ratio, $v^* = V^*/K$. The valuation ratio is endogenous and indicates all the policies should prevent from bubbles ahead. Exogenous inflation shown by *CPI* follows later than bubbles. Bubbles interrupt a steady growth and stop-inequality path, as many countries have experienced. There are *four* patterns defined and each corresponding countries are as follows:

1. Pattern Smooth: $1.0 < v^* < 2.75$ (except for early 1990s), balanced and smooth.
2. Pattern Avoid: $v^* < 1.0$ or $v^* > 4.0$, with steady change in policies.
3. Pattern Policy-Warning: minus v^* included, towards urgent change in policies.
4. Pattern the Lowermost: no value of v^* , revolutionary revival required.

Pattern Smooth: Turkey, Kazakhstan, Indonesia, Philippines, Argentina
(after 2002), Bolivia, Paraguay, and Peru.

Pattern Avoid: Pakistan, Bangladesh, and Mexico.

Pattern Policy-Warning: Ukraine, Sri Lanka, Vietnam, Chile, and Colombia.

Pattern the Lowermost: None.

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

The above countries have known how to guard against instant-oriented funds. The mobility of capital among countries is endogenously guaranteed under a moderate equilibrium. Recall that bubbles earn huge profits at the sacrifice of financial institutions, which must be finally rescued by deficit by country.

BOX 11-4 Characteristics of younger-stage of 16 countries, 1990

1990	The capital-output ratio				1990	$(S_{PRI}-I_{PRI})/Y$ as BOP less deficit

Chapter 11

Notes for BOX 11-3, 11-4, and 11-5:

1. For the last twenty years, each country has taken a different transition, where some countries have taken a more stable path than others.
2. Some countries start with a new step to accept the SNA, where rapid irregular trends disappear within a few years but these results are interesting to know how some ratios are settled at the first step. For example, the capital-output ratio is extremely low and the rate of return is extremely high under different level of the relative share of capital, each in endogenous-equilibrium.
3. Two countries, Ukraine and Kazakhstan, start with 1993 and 1995. These data are exceptionally shown in 1990 data of Figure 2. When data are exceptionally out of each table, these data are input at the corner of top left or bottom right.
4. Policy-makers by country have its own philosophy and decisions to harmonize national taste/preferences with corresponding technological progress. Yet, some of real-assets policies may be wrong, resulting in back and forth trends. Most importantly, actual data should be closer to endogenous data by sector; a stable or fluctuating level of net investment over years determines the differences by country.

Data source: KEWT 5.11-5 by sector, 1990-2009, whose original data are from *International Financial Statistics Yearbook*, IMF. Figures 3, 4, and 5 are based on the same KEWT 5.11-5.

For each set of data by item, see tables by country and area (weighted averaged) in Appendix at the end.

Five pattern-settings by aspect were as explained above, with three sets of figures. The author finds that Pakistan has encountered most difficult times during the last twenty years. Why do Pakistan policy-makers not find moderate combinations of real-assets policies for equilibrium? The author comments on the case of Pakistan by reviewing each of seven endogenous parameters. Apparently, each value of seven endogenous parameters are not so much exceptional except for the DRC coefficient, δ_0 . Pakistan's δ_0 has shown a minus value by year continuously. Years of a plus value of δ_0 are exceptionally 1990, 1999, 2002, and 2008, yet these values are 1.5926, 1.3866, 1.5175, and 1.1940, each abnormally high. What are the causes of abnormal levels of δ_0 ? Two reasons are: (1) The qualitative net investment coefficient is less than 0.5, which implies that $B^* = (1 - \beta^*)/\beta^*$ is above 1.0. (2) The capital-output ratio is less than 1.0.

For these two reasons, the value of δ_0 has been abnormal. Nevertheless, Pakistan's G sector is normal, where low $B^* = (1 - \beta^*)/\beta^*$ is low and the capital-output ratio is high, resulting in normal δ_0 by year. Then, what does this mean? A serious problem stays at the PRI sector. The balance of the G sector and the PRI sector is extreme abnormal. Pakistan policy-makers lost their way how to recover the abnormality at the PRI sector. It is apparently possible for policy-makers to operate the G sector. But, actually this operation is far beyond a limit of the G sector in the case of Pakistan. The G sector and the PRI sector are closely related and cannot overrun a certain level of unbalance between the two sectors. And further, fundamental causes are traced back to

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

minus high levels of the balance of payments and deficit. In this respect, Pakistan's case teaches us a warning against the unbalance between the two sectors. A young organic economy teaches us this fact.

In short, peculiar characteristics of the transition processes to robust-developing are policy-oriented in the endogenous-equilibrium and expressed by dynamic balances between government and private sector. This fact is naturally connected with common characteristics. It implies that it is difficult for young-developing stage countries to clearly distinguish *common* with *peculiar* characteristics.

11.5 Reinhart and Rogoff (2009), Lall (2001), Kuruvilla et al (2002), and Castillo, A. et al (2005): Common v.s. Peculiar Characteristics

This section reviews a few impressive articles to seek the characteristics at young-developing countries common to developed countries. The author understands that common is a concept for long periods while peculiar short and long periods. Author's five pattern-settings are applied to 21 years, 1990-2010, as short periods. Carmen M. Reinhart and Kenneth S. Rogoff (249-273, 2009) devises long periods, 1900-2005/2008, 1800-2008 or 1820-2000, with resultant analyses. Reinhart and Rogoff (*ibid.*; hereunder R & R) surprisingly presents one of most reliable data to us. The researches by R & R are based on four relationships between banking crisis, currency crashes, default, and inflation (BCDI). As a result, R & R develops a composite index called the BCDI Index. This Index is commonly applicable to many countries, developed and developing. The four items of R & R, no doubt, constitute author's 'characteristics common to developed countries and developing countries.' The four items correspond with author's five pattern-settings in this chapter. Five pattern-settings do not step into indexes while the four items of R & R develops the BCDI Index among countries based on country and area data.

The author reviews and introduces three points in R & R (263,*ibid.*). First is Figure 16.7 of R & R (263, *ibid.*). The x axis shows time after of t, t+1, t+2, t+3,..., t+9, t+10, t+11, at global stock markets during global crisis. The y axis shows Composite Real Stock Price Index (End of Period), where Index (t) 2007=100. 11936 is exceptionally high and long. Others are significantly lower and shorter. Second is Figure 16.8 of R & R (264, *ibid.*). The x axis shows time after of t, t+1, t+2, t+3,..., t+9, t+10, t+11, at Real per capita GDP during global financial crisis and, the y axis shows GDP Index, where WEO 2009, Index 2008=100. Figure 16.8 compares Emerging economies, WEO (World Economic Outlook); Advanced economies, WEO; Western Europe; Latin America; and Australia, Canada, New Zealand, United States. GDP recovers promptly and shortly in the case of two WEOs while other three cases sharply fall and then recover gradually. Except for the case of WEO at Figure 16.8, three cases correspond with author's speed years in equilibrium. Supposing that author's neutrality of the

Chapter 11

financial/market assets to the real assets holds, Figure 16.7 is plausibly replaced by real-assets recovery.

Third is Figure 16.12 of R & R (271, *ibid.*). Figure 16.12 shows The sequencing of crises: A prototype. Figure 16.12 is related to i) Diaz-Alejandro; ii) Kaminsky and Reinhart ‘twin crises;’ iii) Capital controls introduced or increased round this time; and iv) Reinhart and Rogoff (2008c) - - no clear sequence of domestic versus external default. I, ii), ii), and iv) are shadowed in Figure 16.12. Figure 16.12 leads to the BCDI Index. Author’s comment is the following: From the viewpoint of financial/market-assets, the prototype is the best in the literature. The prototype exactly corresponds with author’s processes to recover equilibrium from close-to-disequilibrium or disequilibrium. Under the endogenous-equilibrium, the processes are numerically measured directly by seven endogenous parameters or understandably by *five* pattern-settings developed in this chapter. Underlying situations are similar to the prototype. This is because the price-equilibrium directly shows the results although the processes are not clarified. The price-equilibrium and the endogenous-equilibrium are the same and completely overlap. The price-equilibrium only shows results while the endogenous-equilibrium clarifies the processes numerically. In particular, R & R is most close to the endogenous-equilibrium. This is because deficits and debts are a base for the cyclical prototype of R & R. Deficits and debts are a key for connecting the financial/market assets with the real assets. And, deficits and debts are characteristics common to advanced/developed and developing countries. In fact, almost all the countries, according to R & R, have experiences of default and bankruptcy by country after 1800.

Economic stage theories have advanced, one step forwards and half step backwards, after industrial revolution, generation after generation and, from selfish to altruistic. Economic methodologies have freely widened, from micro to macro and, from policies to strategies.

Second, turning to peculiar characteristics, the author briefly reviews Lall, S. (2001). Look at ‘competitiveness indices and developing countries’ by Lall (*ibid.*): Tables 1 to 4 in Lall (1502, 1516, 1517, 1518, *ibid.*) compares two indexes, IMD (2000) and WEF (2000), with such data as categories of variable, R &D, and royalties ranking. Index and ranking differs with its own criterion for competitiveness by country. To solve this problem universally, the author presented an essential ratio analysis at Chapter 8. This chapter, instead of indices, tried to express competitiveness using *five* pattern-settings based on six organic aspects.

Third, the author picks up Singapore assessed by Kuruvilla, S., Erickson, CL., and Hwang, A. (2002). Kuruvilla et al (1461-1476, *ibid.*) investigates a strategy such as skill development system for competitiveness. Strategies must be Blue Birds chosen freely yet, without numerical integration or aggregation of data as a whole system. Skills development is evaluated as results. The endogenous system contrarily needs strategies

Stage Processes from Young-Developing to Robust-Developing by Country in the Endogenous-Equilibrium

to support and reinforce polices. The endogenous system reflects and measures the results of skills development. In this respect, Kuruvilla et al (*ibid.*) is a good work needed for endogenous policies. A problem is how to absorb ‘skills development’ into endogenous policies synthesized as a whole system.

Fourth, the author pays attention to Castillo, A., Magana, A., Pujadas, A., Martinez, L., and Godinez, Z. (2005). Castillo, A. et al (630-643, *ibid.*) investigates ‘rural people with ecosystems’ experimented at a region in Mexico. The experiment presents a typical case of universal policy and strategy. Past three century history of agriculture and industries suggests that this experiment does not end but is deepened nearer to nature, from chemical fertilizer to natural circling fertilizer and, from eroded to fermented soil, body, and society; nearer to nature. Endogenously, the direction expressed by Castillo, A. et al (*ibid.*) is indispensable. Because, the qualitative net investment coefficient measures and realizes that direction most numerically.

Castillo, A. et al (*ibid.*) was expected to be *peculiar* but ultimately resulted in the *common* characteristics.

11.6 Conclusions

Why did some young-developing countries conquer their difficulties and get into the next stage while others stayed at the same stage up and down for many years? Do young-developing stage countries have strong personality of national taste/preferences, culture, and history than developed stage countries? No, strong personality is not the reason why some countries cannot get into the next-stage. *Five* pattern-settings (BOXES 3 to 5, with 32 Tables by country), prove that true causes are unbalanced activities between government and private sectors. It is difficult for young-developing countries to flexibly adjust various priorities of short- and long-term polices, compared with the case of robust-developing countries. This fact identifies a *peculiar* characteristic of young-developing countries. The young-developing stage needs a consecutive high level of net investment over years. Distribution of net investment between public infrastructure and enterprises is delicate. Economic circumstances change quickly and sharply. Net investment and its distribution between government and private sectors need to be long-sighted. Unbalanced periods are indispensable at young-developing countries. Financial support is required consecutively and stably. When real-assets policies do not match financial-assets policies, the speed years are instable and fall into close-to-disequilibrium. Most of young countries, 1990-2010, have severely experienced close-to-disequilibrium.

On the other hand, *common* characteristics of young-developing stage countries are based on the endogenous structure of the balance of payments. Here the author does not repeat deficits and debts to control the balance of payments (see R & R above). If a

Chapter 11

country is instable in endogenously maintaining the balance of payments, its economy becomes instable and cannot get into the next stage. A true fact for the balance of payments is not a high plus level but a stable plus or minus level to some extent. A flexible range of the balance of payments makes the rate of technological progress stable. A high plus level of the balance of payments damages sustainable growth in the long run.

Nevertheless, young-developing stage countries often and sharply fall into a fluctuating level of the balance of payments and result in up and down changes in net investment. The fluctuating level of the balance of payments ultimately comes from unbalanced net investment activities between government and private sector. Sharp changes in net investment are *peculiar* to the young-developing stage; these results constitute characteristics of the young-developing stage. When a country could ride over *peculiar* characteristics, the country gets into robust-developing country.

Once a young-developing country falls into economic difficulties, the tide changes at once and adversely; the market reaction is severe more than at the robust-developing country. Net investment is stabilized by dynamic policies, fast and flexible, but it is difficult for the young-developing countries to execute fast and flexible policies to the real assets. Conclusively, *peculiar* and *common* characteristics are tightly related in the case of the young-developing stage.

When the world economies are stuck after bubbles, waste deficits, and weaken sustainable growth in the long run, enterprise managers cry out money supply much more. Any country cannot fasten international money within the country, once the country turns to the worse and loses its attractiveness to investors. Or, excessive money returns back to central banks. Therefore, ample helicopter money supply in the world remains psychological effect. We need improvement in the real-assets through seven endogenous parameters. We need assessment of five pattern-settings to examine effective policies by country. Then the neutrality of the financial assets to the real assets is strengthened and, the market becomes calm. It implies that an economy cannot survive alone and selfishly. We need cooperation, not fighting but for others. Safely we return back to human original thought and philosophy.

Finally Lewis, Arthur, W. (139-191, 1954; 1978; 1-10, 1984) has, historically and socially, investigated actual environmental causes and results among many countries for so many decades. His experienced viewpoint of trades and prices between two countries is supreme. Analyses in this chapter needs to broadly interpret author's neutrality of the financial/market assets to the real assets and, to review pattern settings and mobility of capital and labor, from his everlasting viewpoint at commodity and industry bases.
